ABSTRACT

Coniothiepinols A (1) and B (2) and coniothienol A (3), the first naturally occurring thiepinols (1 and 2) and thienol (3), have been isolated from the crude extract of an endolichenic fungus *Coniochaeta* sp. 1 possesses a unique 8-oxa-2-thia-bicyclo[3.2.1]octane skeleton, and its structure was assigned by NMR spectroscopy and X-ray crystallography. 1 showed significant activity against the Gram-positive bacteria, *Enterococcus faecium* and *Enterococcus faecalis*.

Analogous to plant endophytes living in the intercellular spaces of the hosts, endolichenic fungi are microbes that inhabit the thalli of lichens.<sup>1</sup> To date, only a limited number of secondary metabolites have been reported from the endolichenic fungi. Examples include five heptaketides isolated from the *Corynespora* sp.,<sup>2,3</sup> ambuic acid and torreyanic acid derivatives from the *Pestalotiopsis* sp.,<sup>4</sup> and allenyl and alkynyl phenyl ethers from *Neurospora terricola*.<sup>5</sup> Our prior chemical study of the endolichenic fungus *Coniochaeta* sp. also afforded six new xanthone derivatives, such

as conioxepinol A (4), a cytotoxic oxepinochromenone, and coniofurol A (5), a furochromenone.<sup>6</sup> The oxepinochromenones and furochromenones (ring-expanded and ring-contracted xanthones, respectively) are relatively rare, with only a few precedents reported prior to our work.<sup>7–11</sup>

Since the crude extract of *Coniochaeta* sp. also showed antimicrobial activities, and its HPLC chromatogram revealed minor components that could not be identified, the fungus was

refermented on a larger scale on rice in which the oxepinochromenones and furochromenones were initially isolated. Bioassay-guided separation of an EtOAc extract afforded two thiepinols, coniothiepinols A (1) and B (2), and a thienol, coniothienol A (3). Details of their structure assignment and antimicrobial activities are reported herein.

Coniothiepinol A (1) was assigned a molecular formula of  $C_{16}H_{14}O_7S$  (10 degrees of unsaturation) by HRESIMS (*m/z* 373.0353 [M + Na]<sup>+</sup>). Its NMR spectra showed resonances for two exchangeable protons, two methyl groups (one methoxy), one methylene, two oxymethines, eight aromatic/olefinic carbons with two protonated, one oxygenated sp<sup>3</sup> quaternary carbon, one carboxylic carbon ( $\delta_C$  166.2), and one  $\alpha_{,\beta}$ -unsaturated ketone carbon ( $\delta_C$  177.2). The <sup>1</sup>H and <sup>13</sup>C NMR data of **1** (Table 1)

revealed the same 5-hydroxy-7-methyl-4*H*-chromen-4-one unit as found in **4** and **5**,<sup>6</sup> but the remaining portion was significantly different. The  ${}^{1}\text{H}{-}^{1}\text{H}$  COSY NMR data of **1** showed the isolated spin-system of C-6–C-8 (including OH-6). HMBC correlations

from H<sub>2</sub>-7 and H-8 to C-8a, and from H-7b to C-5 led to the connections of C-8 to C-8a and C-5 to C-6, respectively. While that from H-8 to C-5 established an ether linkage between C-5 and C-8. Considering the chemical shifts of C-5 ( $\delta_{\rm C}$  96.9) and C-10a ( $\delta_{\rm C}$  165.4), the only sulfur atom in **1** was attached to both carbons to complete a 4,5-dihydro-2*H*-thiepino[2,3-*b*]chromen-6(3*H*)-one skeleton. An HMBC cross peak from H<sub>3</sub>-13 to C-12 connected the C-13 *O*-methyl group to C-12, whereas C-12 was attached to C-5 on the basis of unsaturation requirement, permitting assignment of the plannar structure of **1** as shown.

Finally, 1 was further confirmed by single-crystal X-ray diffraction analysis (Figure 1), and the X-ray data allowed

Figure 1. Thermal ellipsoid representation of 1. (Note: The numbering of structure 1 presented here is consistent with the backbone numbering for 1. A different numbering system is used for the structural data deposited with the CCDC.)

determination of its relative configuration. The presence of a sulfur atom in 1 and the value of the Flack parameter  $0.01(10)^{12}$  determined by X-ray analysis also permitted assignment of the absolute configurations of all the chiral centers as 5*R*, 6*R*, and 8*S*.

Compound **2** was given a molecular formula of  $C_{16}H_{16}O_6S$  by HRESIMS (*m*/*z* 359.0563 [M + Na]<sup>+</sup>). Analysis of its NMR spectroscopic data showed structural similarity to **1**, except that the thiepane ring was different. Specifically, the C-8 oxymethine in **1** ( $\delta_H/\delta_C$  5.79/73.0) was reduced and connected to the methyl formate unit as evidenced by its NMR shifts ( $\delta_H/\delta_C$  3.93/44.6) and HMBC cross peaks from H-8 and H<sub>3</sub>-13 to C-12. While the C-7 methylene in **1** was replaced by an oxymethine ( $\delta_H/\delta_C$  4.25/66.9), and the C-5 oxygenated sp<sup>3</sup> quaternary carbon was replaced by a methylene ( $\delta_H/\delta_C$  2.90/26.8), which were supported by relevant <sup>1</sup>H<sup>-1</sup>H COSY NMR data. Therefore, the gross structure of **2** was determined as depicted.

The relative configuration of **2** was deduced by analogy to **4**.<sup>6</sup> Considering their biogenetic similarity, the C-7 and C-8 stereogenic centers in both compounds presumably have the same configuration, suggesting a *cis* relationship between OH-7 and the methyl formate group, which was partially supported by a NOESY correlation of OH-7 with H<sub>3</sub>-13.

The absolute configuration of the C-7 secondary alcohol in 2 was first assigned via the circular dichroism data of an in situ

<sup>(12)</sup> Flack, H. D. Acta Crystallogr., Sect. A 1983, 39, 876-881.

formed [Rh<sub>2</sub>(OCOCF<sub>3</sub>)<sub>4</sub>] complex,<sup>13</sup> with the inherent contribution subtracted. Upon addition of [Rh<sub>2</sub>(OCOCF<sub>3</sub>)<sub>4</sub>] to a solution of **2** in CH<sub>2</sub>Cl<sub>2</sub>, a metal complex with [Rh<sub>2</sub>(OCOCF<sub>3</sub>)<sub>4</sub>] was generated as an auxiliary chromophore. It has been demonstrated that the sign of the E band at ca. 350 nm can be used to correlate the absolute configuration of a secondary alcohol by applying the bulkiness rule.<sup>13,14</sup> In this case, the Rh-complex of **2** showed a positive E band (Figure 2), correlating to the 7*S* absolute

Figure 2. CD spectra of Rh-complex of 2 with the inherent CD spectrum subtracted.

configuration. Considering the possible interference of the carbonyl functionality, the modified Mosher method was also applied.<sup>15,16</sup> Treatment of **2** with (*S*)- and (*R*)-MTPA Cl afforded *R*-(**2a**) and *S*-MTPA (**2b**) monoesters, respectively. The difference in chemical shift values ( $\Delta \delta = \delta_S - \delta_R$ ) for **2b** and **2a** was calculated to assign the 7*S* configuration (Figure 3). Therefore, the 7*S* and 8*R* absolute configuration

(S)-MPTA esters 2a and 2b, respectively.

was finally assigned for 2 based on the  $\Delta \delta$  results summarized in Figure 3.

Compound **3** gave a pseudomolecular ion  $[M + Na]^+$  peak at m/z 375.0512 by HRESIMS, consistent with the molecular formula  $C_{16}H_{16}O_7S$  (nine degrees of C=C unsaturation). Analysis of its NMR spectroscopic data revealed nearly identical structural features to those of **5**, except that the chemical shifts of the C-7 oxymethine in **5** ( $\delta_H/\delta_C$  5.33/91.6) were different from those of its counterpart in **3** ( $\delta_H/\delta_C$  4.59/56.7). In addition, the chemical shift of the C-10a

sp<sup>2</sup> quaternary carbon in **3** ( $\delta_{\rm C}$  176.2) is also different from that of **5** ( $\delta_{\rm C}$  171.0). Collectively, C-7 and C-10a were both attached to the sulfur atom to establish a 2*H*-thieno[2,3-*b*]chromen-4(3*H*)-one frame, completing the gross structure of **3**.

The relative configuration of **3** was determined on the basis of NOE data. Upon irradiation of H-7 in the NOE experiment, enhancement was observed for H<sub>3</sub>-13, suggesting their *cis* relationship, which is consistent with that of **5**. The absolute configuration of the C-8 tertiary alcohol was also first deduced via the CD data of the [Rh<sub>2</sub>(OCOCF<sub>3</sub>)<sub>4</sub>] complex as described for **2** and **5**.<sup>6</sup> The Rh-complex of **3** showed a positive E band near 350 nm (Figure S9, Supporting Information), revealing the 8*S* absolute configuration. Although this assignment could not be verified, the 7*R* and 8*S* absolute configuration was deduced for **3** considering its biogenetic similarity to **5**.

Compounds 1–3 were tested for activity against the Grampositive bacteria, *Enterococcus faecium* (CGMCC 1.2025) and *Enterococcus faecalis* (CGMCC 1.2535), and the plant pathogenic fungus *Fusarium oxysporum* (CGMCC 3.2830) (Table 2). Com-

	$IC_{50} (\mu g/mL)$			
compd	E. faecium	E. faecalis	F. oxysporum	
1	$3.93\pm0.18$	$11.51\pm0.45$	$13.12\pm0.46$	
2	>20	>20	>20	
3	$2.00\pm0.06$	$4.89\pm0.19$	>20	
ampicillin	$0.51\pm0.014$	$2.61\pm0.23$		
carbendazim			$0.44\pm0.008$	

pound **3** showed significant activity against *E. faecium* and *E. faecalis*, with IC<sub>50</sub> values of 2.00 and 4.89  $\mu$ g/mL, repectively, while the positive control ampicillin showed IC<sub>50</sub> values of 0.51 and 2.61  $\mu$ g/mL, respectively. Although **1** is less potent than **3** against the bacteria, it displayed modest antifungal activity against the plant pathogen *F. oxysporum*.

Although *S*-containing natural products have been isolated frequently from fungal sources, coniothiepinols A (1) and B (2) and coniothienol A (3) are the first naturally occurring thiepinols (1 and 2) and thienol (3), respectively. Compounds 1 and 2 possess the unique 4,5-dihydro-2*H*-thiepino[2,3-*b*]chromen-6(3*H*)-one skeleton, with 1 incoporating the 8-oxa-2-thia-bicyclo[3.2.1]octane partial structure due to the presence of C-5–C-8 ether linkage.
